## Iterative Methods to Solve The Equation $f(x) = 0$

Given a continuous function  $f$ , the goal of this chapter is to estimate the solution of the equation  $f(x) = 0$  in a certain interval  $I$  numerically.

**Theorem 1.0.1** (Intermediate Value Theorem). *Let  $f : [a, b] \rightarrow \mathbb{R}$  be a continuous function. Let  $y \in \mathbb{R}$  be any value between  $f(a)$  and  $f(b)$ . Then there exists  $z \in [a, b]$  such that  $f(z) = y$ .*

Bolzano's Theorem is a special case of the Intermediate Value Theorem, which states

**Theorem 1.0.2** (Bolzano's Theorem). *If a continuous function defined on an interval  $I$  is sometimes positive and sometimes negative, then it must be 0 at some point. So there exists  $x_0 \in I$  such that  $f(x_0) = 0$ .*

*Proof.* Without loss of generality, assume  $f(a) \leq f(b)$ . Let  $y \in [f(a), f(b)]$ . Set

$$S := \{x \in [a, b] : f(x) \leq y_0\}$$

$S$  is a subset of  $[a, b]$  so it is bounded,  $a \in S$  since  $f(a) \leq y_0$ . Therefore  $S \neq \emptyset$ . Thus by completeness, there exists  $x_0 := \sup S \in [a, b]$ . We want  $f(x_0) = y_0$ . Consider the cases where  $f(x_0) = y_0$ ,  $f(x_0) < y_0$ , and  $f(x_0) > y_0$ .

- **Case 1:**  $f(x_0) = y_0$  This case is trivial since this is the result we want.
- **Case 2:**  $f(x_0) < y_0$  Set  $\epsilon := y_0 - f(x_0)$ . Since  $f$  is continuous at  $x_0$ ,  $\exists \delta > 0$  such that

$$|x - x_0| < \delta \implies |f(x) - f(x_0)| < \epsilon$$

Since  $f(x_0) < y_0 \leq f(b)$ , we can find  $x > x_0$  such that  $x \in [a, b]$  and  $|x - x_0| < \delta$ . Then  $f(x) < f(x_0) + \epsilon = y_0$ . So  $x \in S$  by the definition of  $S$ , but  $x > x_0$  which contradicts the fact that  $x_0 = \sup S$ .

- **Case 3:**  $f(x_0) > y_0$  Set  $\epsilon := f(x_0) - y_0$ . Since  $f$  is continuous at  $x_0$ ,  $\exists \delta > 0$  such that if  $x \in [a, b]$  and  $|x - x_0| < \delta$ , then  $|f(x) - f(x_0)| < \epsilon$ . So  $f(x) > f(x_0) - \epsilon = y_0$  and  $x_0 > a$ . We can assume that  $x - \delta > a$  since  $\delta$  can be arbitrarily small, and we claim  $x_0 - \delta$  is an upper bound for  $S$ . To prove this, if  $x > x_0 - \delta$ , then either  $|x - x_0| < \delta$ , in which case  $f(x) > f(x_0) - \epsilon = y_0$ , or  $x > x_0$  then  $x \neq S$  since  $x_0$  is an upper bound for  $S$ . Therefore, if  $x > x_0 - \delta$ , then  $x \neq S$ , thus proving the claim. This contradicts that  $x_0$  is the supremum of  $S$ .

□

**Example:** Prove that the equation

$$2x^3 + 2x - 4 = 0$$

has a unique root in  $[0, 1]$ .

*Proof.* Set  $f(x) := 3x^2 + 2x - 4$ , this function is continuous since it is a polynomial. We have  $f(0) = -4 < 0$  and  $f(1) = 1 > 0$ , so by the intermediate value theorem, there exists  $c \in [0, 1]$  such that  $f(c) = 0$ . It follows that  $c$  is unique since the polynomial is injective by virtue of  $x^3$  and  $x$  being injective. □

## 1.1 Fixed-Point Iteration

**Definition 1.1.1.** We say that the value  $x = r$  is a fixed point for a function  $g(x)$  if  $g(r) = r$ .

**Example:**  $g(x) = \frac{5-x^2}{4}$ .  $r = 1$  is a fixed-point for  $g$  since  $g(1) = 1$ .

Graphically, fixed-point of  $g(x)$  correspond to the intersection of the graph of  $g(x)$  and the line  $y = x$ . Given an equation  $f(x) = 0$ , we can write it under the form

$$g(x) = x$$

by isolating one  $x$  in the equation.

**Example:**  $3x^3 + 2x - 5 = 0$ . We can write this as

$$x = \frac{5 - 3x^3}{2}$$

Set  $g(x) := \frac{5-3x^3}{2}$ . Then  $g(x) = x$ . Finding a root for  $f(x) = 0$  is equivalent to finding a fixed-point for  $g(x)$ .

### 1.1.1 Steps to Solving Using Fixed-Point Iteration

Start with a first estimation  $x_0$  (will be given) of the root, and form the following sequence (known as the *iteration sequence*)

$$x_0, x_1 = g(x_0), x_2 = g(x_1), \dots, x_n = g(x_{n-1})$$

If this sequence converges to a value  $a$ , then we can prove that  $a$  is a fixed-point for  $g$ , hence a root for  $f(x) = 0$ .

**Theorem 1.1.1.** *Assume that the function  $g$  has a fixed-point  $s$  on an interval  $I$ , if*

- (i)  $g(x)$  is continuous on  $I$
- (ii)  $g'(x)$  is continuous on  $I$
- (iii)  $|g'(x)| < 1$  for all  $x \in I$

The steps for solving are as follows

1. Start with  $f(x) = 0$
2. Rewrite  $f(x) = 0$  under the form  $x = g(x)$
3. Verify that the sequence  $x_0, x_1 = g(x_0), x_2 = g(x_1), \dots, x_n = g(x_{n-1})$  converges using the above theorem (or otherwise)
4. Compute terms of the above sequence and stop when you reach the required accuracy

**Example:** Consider the equation

$$x^3 + 12x - 3 = 0$$

1. Prove that the equation has a unique root in  $[-1.9, 1.9]$
2. Use the Fixed-Point iteration method to estimate the value of the root to 6 decimal points starting with  $x_0 = 1.8$

**Solution:** Using the steps, we have

1. Set  $f(x) := x^3 + 12x - 3$ . Since  $f(x)$  is a polynomial, it is continuous, so by the intermediate value theorem, we have there exists  $c \in [-1.9, 1.9]$  such that  $f(c) = 0$ .  $f(x)$  is injective since  $x^3$  and  $x$  are injective, so  $c$  is unique.
2. Set  $g(x) := \frac{3-x^3}{12}$ .
3. Checking the conditions of the theorem,  $g(x)$  is continuous since it is a polynomial,  $g'(x) = -\frac{x^2}{4}$  is continuous since it is a polynomial. Then

$$|g'(x)| = \frac{x^2}{4} \leq \frac{1.9^2}{4} = 0.902 < 1$$

Therefore, the sequence converges.

4. We have to calculate the terms of the iteration sequence,

$$x_0 = 1.8$$

$$x_1 = g(x_0) = \frac{3 - 1.8^2}{12} = -0.236000$$

$$x_2 = g(x_1) = \frac{3 - (0.236)^2}{12} = 0.251095$$

$$x_3 = g(x_2) = \frac{3 - (0.251095)^2}{12} = 0.24861$$

$$x_4 = g(x_3) = \frac{3 - (0.24861)^2}{12} = 0.248718$$

$$x_5 = g(x_4) = \frac{3 - (0.248718)^2}{12} = 0.248718$$

We stop when 2 consecutive terms agree on the first 6 decimal points. So the root is 0.248718 correct to 6 decimal points.
